

HBT DIGITAL PHASE-FREQUENCY DETECTOR, 10 - 1300 MHz, w/ INTEGRATED 5-BIT COUNTER, 10 - 2800 MHz

Typical Applications

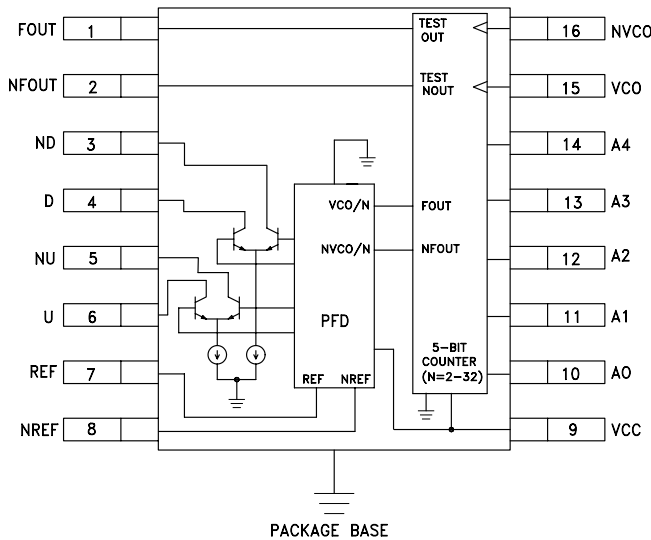

This Phase Frequency Detector w/ integrated Counter is a key component in low phase noise frequency synthesis applications such as:

- Satellite Communication Systems
- Pt-Pt Radios
- Military Applications
- Sonet Clock Generation

Features

- Ultra Low SSB Phase Noise Floor:
-153 dBc/Hz @ 10 kHz offset @ 100 MHz Reference Frequency.
- Programmable Divider (N= 2-32) Operating up to 2.8 GHz
- Open Collector Output Buffer Amplifiers for Interfacing w/ Op-Amp Based Loop Filter
- QSOP16G SMT Package: 29.4 mm²

Functional Diagram

General Description

The HMC440QS16G integrates a 10 to 1300 MHz digital Phase-Frequency Detector with a 10 to 2800 MHz 5-Bit Counter (continuous division from 2 to 32) in a miniature 16 lead QSOP plastic package. It is intended for use in low phase noise offset-synthesizer applications. The HMC440QS16G's combination of high frequency operation along with ultra low phase noise floor make possible synthesizers with wide loop bandwidth and low N resulting in fast settling and very low phase noise. When used in conjunction with a differential loop amplifier, the HMC440QS16G generates an output voltage that can be used to phase lock a VCO to a reference oscillator.

Evaluation PCB

The circuit board used in the final application should use RF circuit design techniques. Signal lines should have 50 ohm impedance while the package ground leads and backside ground slug should be connected directly to the ground plane similar to that shown. A sufficient number of via holes should be used to connect the top and bottom ground planes. The evaluation circuit board shown is available from Hittite upon request.

Evaluation PCB Truth Table

Note: The evaluation PCB for the HMC440QS16G contains 10K Ohm pull up resistors for each of the five control inputs A0 through A4. Programming the 31 distinct division ratios consists of installing or removing jumpers S1 through S5, as shown below.

Applications Information

Simplified Block Diagram of 5-Bit Counter

Asynchronous Programming

The 5-Bit programmable counter counts-down from the programmed value of the data bits to zero and issues an output pulse at the end of each cycle. Settling time of the programmable 5-Bit counter is defined as the maximum time required for the counter to change the division ratio N to a new value after the data bits have settled. The worst case settling time occurs if the data bits A0 thru A4 are changing during the load cycle. Under this condition, the data bits may potentially be erroneous when they are clocked in and in the worst case could be all 1's, requiring 32 clock cycles until the correct data is re-loaded into the flip flops. The worst case asynchronous settling time can be calculated as follows:

$$T_{\text{SETTLING MAX}} = 32/f_{\text{IN}} \text{ (For Asynchronous Programming)}$$

As an example, if the input frequency is 1 GHz, the maximum settling time is 32 nS

Synchronous Programming

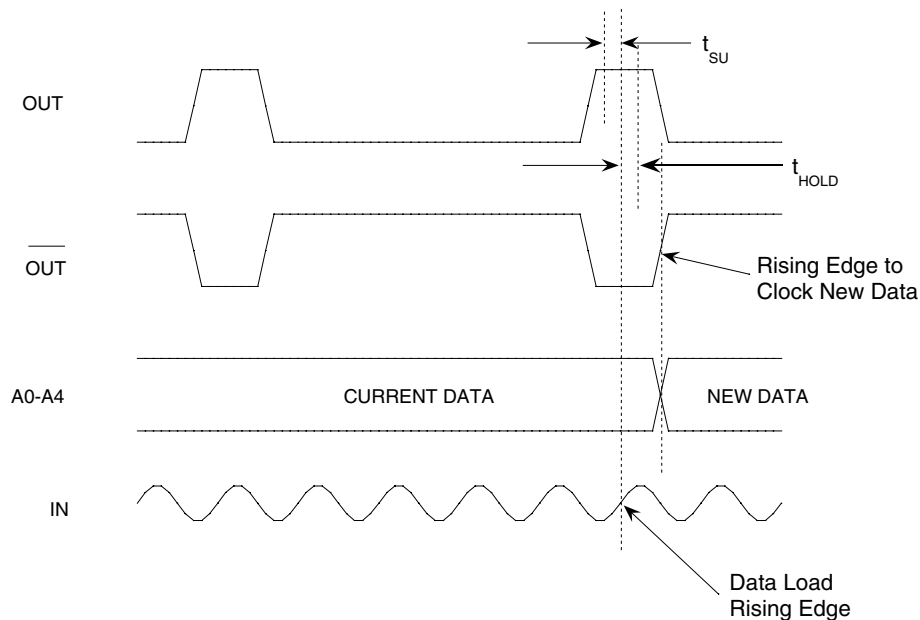

For applications which can not tolerate a momentary undefined division ratio, which normally occurs while changing the data bits (A0-A4) at random, synchronous programming can be used. Data is loaded into the counter on every rising edge of the clock which occurs while the output (OUT) is "HIGH". The typical minimum setup and hold times are shown in the table below as a function of frequency. For precision applications, the rising edge of the complementary output may be used to latch the new data bits (A0-A4), so that all bits are settled before the next load cycle.

$$T_{\text{SETTLING MAX}} = N/f_{\text{IN}} \text{ (For Synchronous Programming)}$$

Where N is the desired division ratio, and f_{IN} = Input Frequency (Hz)

Parameter	0.5 GHz	1 GHz	2 GHz
t_{SETUP}	200 ps	200 ps	200 ps
t_{HOLD}	700 ps	300 ps	120 ps
